1. INTRODUCTION

For the 2008 Adult California Tobacco Study (CTS), Westat performed statistical tasks that included sample selection, weighting, and data collection. This volume of the report contains a description of the methodology used by Westat to do sample selection, weighting, and develop replicate weights for variance estimation purposes.

Two different instruments—the Screener and Adult instruments—were developed by UCSD and Westat for the 2008 Adult CTS to provide data that would be comparable to the 1990, 1992, 1993, 1996, 1999, 2002, and 2005 CTS surveys. Details on the 2008 instruments can be found in the *2008 Adult California Tobacco Study Description of Methodology: Volume I: Data Collection Methodology*.

The 2008 Adult CTS utilized the list-assisted RDD method to screen eligible telephone households. This method significantly reduces the cost and time involved in such surveys in comparison to dialing numbers completely at random.

The general approach employed is a two-stage sampling procedure in which a sample of 22,225 households were screened to obtain demographic information, including the smoking status of all household members who were 10 years and older. At the second stage, extended interviews were attempted with a random sample of adults 30 years or older (sampling rate was based on the smoking status and race/ethnicity) and all young adults (18 to 29 years).

2. SAMPLE SELECTION

Households in California that had at least one adult (aged 18 years old or older) were selected for the 2008 Adult CTS by a random digit dialing (RDD) procedure known as the “list-assisted” sampling method. Under the list-assisted sampling method, random samples of telephone numbers were selected from banks of 100 telephone numbers that were known to contain at least one *listed* residential telephone number. Those banks with at least one listed residential telephone number are referred to as “1-plus working banks.”

Nationally, only 20 percent of all numbers are working residential numbers; however about 40 percent of telephone numbers in 1-plus working banks are residences (households). Use of 1-plus working banks in the list-assisted sampling approach is not without a cost, however. The “cost” is the potential bias resulting from the exclusion of some unlisted residential telephone numbers in the “zero banks” and some residences in “new-banks.” Fortunately, less than 4 percent of all telephone households (nationally) would be excluded from this sampling process.

The first step in the list-assisted sampling process involved identifying those area codes/exchanges that had any households in the target areas of interest, the 12 California regions. The process of mapping area codes/exchanges into small geographical areas was not always straightforward, because telephone exchanges straddled county boundaries. The sampling frame vendor (GENESYS) provided 12 *exchange coverage reports* containing all the exchanges that covered each of the 12 California study regions. There were some overlaps¹ of exchanges among the coverage reports. Every exchange in the coverage report was associated with a *county of plurality* (i.e., the county that had the highest percentage of listed numbers in the exchange) in the telephone numbers database provided to Westat by GENESYS. For sampling purposes exchanges were assigned to unique regions based on the county of plurality measure. Moreover, a few exchanges that had very high density of pagers and other nonresidential hand held devices were omitted. The GENESYS database system did not contain these exchanges. The exchanges that were not considered for sampling purposes covered less than 1 percent of all the exchanges that contained the 1-plus working banks covering the State of California.

¹ About 90 percent of the exchanges covered single regions and about 10 percent of the exchanges covered two or more regions.

The second step in the list-assisted sampling process involved assigning area codes/exchanges in Los Angeles County to either a high minority stratum, denoted as stratum 1H, or a low-minority stratum, denoted as stratum 1L. We used the exchange-level data variable *pctblack* to stratify the telephone exchanges in Los Angeles County. This variable contained the proportion of an exchange's population that was Black. It was provided by GENESYS, who derived it from 2000 Census data and updated it with intercensal sample data. Los Angeles County telephone exchanges were assigned to stratum 1H if *pctblack* exceeded 25 percent and to stratum 1L if *pctblack* was less than or equal to 25 percent

The third step in the sampling process involved selecting a stratified sample of telephone numbers. There were 13 strata: 1-H and 1-L, plus 11 strata corresponding to the 11 regions other than Los Angeles County.

Based on residency rates and response rates in 2005, a preliminary estimate of about 288,000 numbers (before GENESYS-CSS purge) appeared necessary. It is standard practice to over-sample telephone numbers by about 50 percent and release a smaller random portion to the Telephone Research Center and keep the remainder as a reserve sample. An additional 144,000 numbers were assigned to a reserve sample. Because the actual number of sample numbers required was much greater than the preliminary estimate of numbers needed, all 144,000 numbers in the reserve sample were released to the Telephone Research Center.

After a household was successfully screened, all adults living in the household were subjected to within-household sampling to determine who would be contacted for extended interviews. All young adults, aged 18 to 29, were selected for extended interviews. Also, all older adult smokers (i.e. current, recent-former, and five-year-former smokers) were selected for an extended interview. The proportion of older adult non-smokers (i.e. long-term quitters or zero or small-amount smokers) selected for an extended interview was 100 percent for Blacks and initially was 40 percent and 10 percent for Asians and all other races, respectively. In the middle of the data collection period, the proportion of older-adult Asian nonsmokers selected for an interview was increased to 67.65 percent, and near the end of the data collection period the proportion interviewed for older-adult Asian nonsmokers was increased again to 100 percent. The proportion of older-adult nonsmokers of all other races was decreased in the middle of the data collection period to 6.71 percent. See Section 3.6 for the overall retention rates used in calculating person-level weights.

In the 2005 Study, all screener refusals were assigned to refusal conversion. In the 2008 Adult CTS, however, a subsampling procedure was used to assign screener refusals to the refusal

conversion team. Subsampling of screener refusals was implemented by pre-assigning conversion status to the individual release groups, which are random sub-samples of the entire telephone sample and are released in sequence to the Telephone Research Centers. Screener refusals in release groups that were pre-assigned conversion status were assigned to refusal conversion, whereas screener refusals in release groups pre-assigned to non-conversion status were deleted from the sample. At the beginning of the data collection period, 80 percent of the release groups were assigned to conversion status. In the middle of the data collection period, the conversion assignments for release groups that had not been released were changed so that 40 percent of these release groups were assigned to conversion status. Approximately 55 percent of the screener refusals were assigned to refusal conversion. All extended-interview refusals were assigned to refusal conversion.

3. WEIGHTING

3.1 Imputation

Four demographic variables—age, gender, race and education—were imputed if the item was missing. There were numerous reasons for item nonresponse. Some respondents did not know the answer for the item or did not wish to respond for other reasons. Some item nonresponse arose when a screener interview was interrupted and not continued later, leaving items at the end of the interview blank. Item nonresponse might have also been encountered because responses provided by the respondent were not internally consistent and this type of inconsistency was not discovered until after the interview was completed. In these cases, the items that were not internally consistent were usually set to missing (or, not ascertained) during the data editing.

Imputations were done for two reasons.

1. Complete responses were needed for variables used in developing the sampling weights; and
2. Users of the data will be computing estimates using a variety of methods and complete responses aid their analyses.

But the primary purpose of item imputation was to develop sampling weights.

The order of imputation was arranged such that certain variables were imputed first so that they could be used to create cells for weighting class adjustments and for subsequent imputation. In cases in which a sort variable within a given file had missing values for some cases, all other sort variables without missing values were used to impute the sort variable with missing values prior to continuing with subsequent stages of imputation.

Prior to weighting, all missing values of four key demographic variables—gender, race, age, and education—were imputed. As in the past California Tobacco Surveys, the missing values of gender, race, age, and education in the screener file were imputed in two steps.

1. The key demographic values from the adult interview, (gender, race, age, and education) were used to overwrite any missing data in the screener file. That is to say that, if, during the screener interview, the screener respondent did not know the age or education level of another household member, and that household member was

selected for an interview, then the age or education information would overwrite the missing data item in the screener file; and

2. Using Westat's hot-deck imputation macro, WESDECK, all remaining missing screener values were imputed.

Once all missing screener-weighting items had been imputed, the imputed screener values were used to replace the missing demographic value missing in any of the extended interview files.

3.2 Weighting Overview

The process of weighting refers to the computation of case-specific sampling weights that are necessary for producing almost unbiased estimates of the population parameters of interest. The weights are needed in the statistical analysis to compensate the variable probabilities of inclusion in the sample. Even for samples in which units are selected with equal probabilities, weighting may still be necessary to compensate for differential rates of nonresponse and deficiencies in the sampling frame. Weighting complex survey data, such as the data from this study, generally involves many steps. Computation of sampling weight components for the 2008 Adult CTS was analogous to that used for the previous CTS. The most important steps for this study are the determination of overall probabilities of selection and calculation of base weights, calculation of household weights, person-level weights, ratio adjustment (raking), and development of replicate weights.

3.3 Base Weights

The base weight of a sampling unit is defined as the reciprocal of the probability of selecting that sampling unit. The base weights are unbiased in the sense that the expected value of a weighted estimate based on the sample data is equal to the corresponding population value that would have been obtained if all the units (rather than a sample) in the frame were surveyed. A noncoverage bias results because the RDD sampling methodology excludes some eligible households.

In the list-assisted RDD method, we used an equal probability of selecting telephone numbers within each stratum. The stratum weight for a sampled telephone number is $w = 1/f$, where f is the stratum sampling rate. If a simple random sampling scheme was used within a stratum, the probability of selecting n telephone numbers from a pool of N numbers is $f = n/N$.

With the use of list-assisted telephone sampling frame, all telephone numbers in a stratum have the same overall probability of selection. Thus, the probability that a household with m telephone numbers will be included in the sample is simply fm , where f is the stratum sampling rate for the pool of numbers generated from the working banks of 1 or more listed numbers.

A total of 22,225 households that had persons 18 years and older in California were successfully screened based on 432,206 telephone numbers selected by the 1-plus list-assisted sampling scheme. The sampled phone numbers were selected from sampling frames associated with 13 strata: high- and low-minority strata for Los Angeles County, plus 11 strata for the 11 regions other than Los Angeles County. Equal probability samples of telephone numbers were selected from each of the 13 sampling frames.

The base weight of a sampled telephone number is the inverse of its probability of selection and is calculated by using the following formula

$$b_i = \frac{N_i}{n_i}, i = 1, \dots, 13;$$

where

N_i = total number of available telephone numbers in stratum i ; and

n_i = number of telephone numbers sampled from stratum i .

3.4 Adjustment to Base Weights to Account for Subsampling Screener Refusals

Because of the subsampling of screener refusals, it was necessary to adjust the base weights to account for this additional sampling. This adjustment only needed to be performed for households that initially refused to complete a Screener. Let

S_0 = the set of household phone numbers whose screener status was resolved at the initial screening effort. These include households that initially cooperated, or were determined to be ineligible or not a residence, or were never contacted;

S_1 = the set of screener households that initially refused and were assigned to refusal conversion; and

S_2 = the set of screener households that initially refused and were not assigned to refusal conversion.

In other words, the adjustment of base weights was necessary only for households in S_1 and S_2 . The households in S_2 received an adjusted base weight of zero because they were deselected from the sample. Within each stratum, the unadjusted base weights of the households in S_2 were distributed to the households in S_1 by calculating adjusted base weights for the S_1 households in the stratum by using the following formula:

$$\begin{aligned}
 b'_{ij} &= \text{adjusted base weight for household } j \in S_1 \text{ in stratum } i \\
 &= b_i(m_{i1} + m_{i2})/m_{i1}
 \end{aligned}$$

where m_{i1} is the number of stratum i households in S_1 and m_{i2} is the number of stratum i households in S_2 . For surveyed households in S_0 , the adjusted base weights are equal to the unadjusted base weights.

3.5 Household Weights

Since we had drawn equal probability samples of telephone numbers from each sampling frame of all available telephone numbers, we assumed the residency rates² for the sample were the same as the corresponding residency rates for all numbers in the sampling frames. If one assumes that every residence had exactly one residential telephone number, then the household weight of a household would be the same as the base weight of the corresponding telephone number. The screener interview, however, included a set of questions about the number of residential landline telephone numbers present in a household. Based on these responses, sample weights were computed to appropriately reflect the probability of selection for households with multiple residential landline phone numbers. A weighting factor of unity was assigned to households reporting one landline telephone number in the household and an adjustment factor of 1/2 is assigned to households with two phones and an adjustment factor of 1/3 is assigned to households with more than two residential telephone numbers. Technically, if the other telephone number(s) of households with multiple residential telephone numbers was in the zero-listed stratum, the household should get a weight adjustment of 1. However, the practice of looking up the other phone numbers in these households was impractical and the percent of such numbers in the zero-listed stratum is small. Eventually, the j -th household in the i -th stratum received a weight of:

² Residency rate is the percentage of telephone numbers leading to households.

$$h_{ij} = \begin{cases} b'_{ij}A & \text{if the household has more than one telephone number} \\ b'_{ij} & \text{if the household has only one telephone number} \end{cases}$$

where

- A = multiple phone adjustment factor; and
- b'_{ij} = the adjusted base weight for a sampled telephone number j in stratum i .

The household weights were copied to both weighting files—the screener file and the adult file.

3.6 Person-Level Weights

As in the past CTS, all the household members were enumerated. Based on age and smoking status, a subsample of the eligible household members was selected for an extended interview. The k -th member of the j -th household in the i -th substratum of a specific region was subsampled at a rate r_{ijk} :

$$r_{ijk} = \begin{cases} 0 & \text{if the } k\text{-th member is not an adult (17 yrs or younger)} \\ a_k & \text{if the } k\text{-th member is an adult (18 yrs or older)} \end{cases}$$

$$a_k = \begin{cases} 1.0000 & \text{if the } k\text{-th member is a young adult (18 to 29 yrs)} \\ 1.0000 & \text{if the } k\text{-th member is an older adult (30 yrs or older) \& \text{ smoker} \\ 0.9641 & \text{if the } k\text{-th member is an older adult (30 years or older), nonsmoker \& \text{ Black} \\ 0.7492 & \text{if the } k\text{-th member is an older adult (30 years or older), nonsmoker \& \text{ Asian} \\ 0.0716 & \text{if the } k\text{-th member is an older adult (30 years or older), nonsmoker \& \text{ Hispanic} \\ 0.0666 & \text{if the } k\text{-th member is an older adult (30 years or older), nonsmoker \& \text{ White} \\ 0.1110 & \text{if the } k\text{-th member is an older adult (30 years or older), nonsmoker \& \text{ Other} \end{cases}$$

Note that for weighting purposes, smokers included both current and former smokers (in the last 5 years); nonsmokers were the people who never smoked or who were long-term quitters (5 or more years of abstinence). By race/ethnicity, we assigned “Black” for people who responded Black alone or Black along with another race; “Asian” for people who responded Japanese, Chinese, Filipino, Korean, Vietnamese, or Other Asian or Pacific Islander alone or along with other race categories; “Hispanic” for people who responded Mexican, Mexican American, or Other Hispanic or Latino to the ethnic background question or responded Mexican or Hispanic/Latino alone or along with other race categories.

The person-level weights were constructed for all the eligible household members. The person-level base weight of the k -th member of the j -th household in the i -th substratum of a specific region is w_{ijk} , where

$$w_{ijk} = \begin{cases} 0 & \text{if } r_{ijk} = 0; \text{ and} \\ h_{ij}/r_{ijk} & \text{if } r_{ijk} > 0. \end{cases}$$

4. RATIO ADJUSTMENT (RAKING)

Theoretically, if the sample was strictly obtained by a probabilistic scheme and there is no nonresponse, then the total of the sample weights should be the population total. But in practice, this is not so due to many factors. Two important factors that contribute to the deviation of weights are nonresponse and noncoverage due to sampling only telephone households covered by selected telephone exchanges. Forcing the weights to known population totals could reduce the effect of nonresponse and noncoverage. This technique is called poststratification and it is a popular estimation procedure in which the weights of the respondents are adjusted so that the sum of the adjusted weights is equal to known population totals.

Since poststratification involves adjusting the weights of the respondents, the poststratified estimates are different than the estimates produced without poststratification and the variances of the estimates are also different. Poststratification is often used to reduce the variance of the estimates. Since poststratification is used so frequently and it affects the estimates and their precision, a facility for poststratifying weights has been generally incorporated in software that analyze complex survey data, such as WesVarPC (available for free from Westat).

Indexing the cell identifiers by c , where $c=1, \dots, L$ (for example region by the age by gender cells), the weights are first summed by cell

$$\hat{W}_c = \sum_{i \in c} w_i,$$

where w_i is the weight of the respondent i that fell in cell c .

Next, the multiplicative poststratification adjustment factor for cell c is computed as

$$A_c = \frac{N_c}{\hat{W}_c},$$

where N_c is the control total for cell c .

The poststratified weight is the weight multiplied by the poststratification adjustment factor corresponding to the correct cell:

$$PW_{i(c)} = A_c w_i \text{ for } i \in c .$$

Raking ratio estimation, or simply raking, can be considered as poststratification performed iteratively in order to control two (or more) known marginal population totals. Raking was first proposed by Deming and Stephan (1940) as a way of assuring consistency between complete count and sample data from the 1940 U.S. Census of Population. Typically, raking is used in situations where the interior cells of a cross tabulation are either unknowns, or some sample sizes in the cells are too small for efficient estimation. Oh and Scheuren (1987) provide a concise description of the raking procedure and its properties.

In raking, the marginal population totals, N_i and N_j are known (say, age, and sex population counts), however, the interior cells of the cross-tabulation N_{ij} (the age by sex cells) are estimated from the sample by \hat{N}_{ij} , where these are the sum of the weights in the cells. The raking algorithm proceeds by proportionately scaling the \hat{N}_{ij} , such that the following relations are satisfied:

$$\sum_j \hat{N}_{ij} = N_i ,$$

and

$$\sum_i \hat{N}_{ij} = N_j .$$

It has been shown (e.g., Ireland and Kullback, 1968) that, under some regularity conditions if only the N_i and N_j are known, then the estimates, \hat{N}_{ij} , obtained by raking to convergence are asymptotically unbiased, normally distributed and minimum variance.

The person-level weights were raked to recent California population counts. The needed controls are presented in the Attachment in Tables A-1 through A-13.

4.1 Screener Sample

All screened households were assigned their household-level weights, h_{ij} . These base weights were raked in five dimensions. The first dimension was defined by region and gender. The second dimension was gender and age categories (0-11, 12-17 and 18+). The third to fifth dimensions

were two-way tables formed by cross classifications of race (Hispanic, White, Black, and other), age (0-11, 12-17, 18-24, 25-44, and 45+), and education (0-11, 12, and 13+). Tables A-1 to A-5 in the attachment contain the control counts.

4.2 Adult Sample

All adults were assigned their person-level weight, w_{ijk} , described in Section 3.6. These weights for adults were raked in eight dimensions. The first dimension was defined by region and gender. The second to fourth dimensions were defined by two-way classification tables of race, age, and education. The fifth to eighth dimensions were smoking status by education, gender, age, and race. The control totals used for these dimensions are described in Tables A-6 to A-13.

The raking dimension tables in the attachment show the source of data for each raking dimension. The external population control totals were derived from the Current Population Survey (CPS) March 2008 Annual Demographic file, the same data source as prior CTS cycles. The raking variables and dimensions for 2008 CTS were the same as those for 2005 CTS, with the exception that for 2008 CTS there was additional collapsing of education.

5. VARIANCE ESTIMATION

When data are collected as part of a complex sample survey, there is often no easy way to produce approximately unbiased and design-consistent estimates of variance analytically. The variance of survey statistics, including means and proportions, estimated using standard statistical packages such as SAS or SPSS, are inappropriate and usually too small. A class of techniques called *replication methods* provides a general method of estimating variances for the types of complex sample designs and weighting procedures usually encountered in practice. The basic idea behind the replication approach is to select subsamples repeatedly from the whole sample, to calculate the statistic of interest for each of these subsamples, and then to use the variability among these subsample or replicate statistics to estimate the variance of the full sample statistics. There are different ways of creating subsamples from the full sample. The subsamples are called *replicates* and the statistics calculated from these replicates are called *replicate estimates*.

Replication is not the only way to compute the variance of statistics from complex samples; however, it is able to handle complex sampling designs, complex estimates, and complex weighting schemes. Replication can be used where other methods are not easily applicable. This method also has some advantages even when other methods, such as Taylor series approximation, can be applied.

One of the main advantages of the replication approach is its ease of use at the analysis stage. The same estimation procedure is used for the full sample and for each replicate. The variance estimates are then readily computed by a simple procedure. Furthermore, the same procedure is applicable to most statistics desired such as means, percentages, ratios, correlation, and so forth. These estimates can also be calculated for analytic groups or subpopulations. It is not even necessary for the analyst to understand the sampling or estimation methods if the replicate weights are included with the data.

Analogous to the previous CTS, the jackknife method of replication was used for estimation of sampling errors for the 2008 Adult CTS. This method employs the full sample estimate, $\hat{\theta}$, and replicate estimates, $\hat{\theta}_r$, ($r = 1, \dots, R$) for a parameter of interest, θ , to estimate the sampling error of $\hat{\theta}$ as follows:

$$v(\hat{\theta}) = \frac{R-1}{R} \sum_{r=1}^R (\hat{\theta}_r - \hat{\theta})^2.$$

In order to remain consistent with the replicate structure of the previous CTS surveys, a set of 51 replicate groups were generated. The data file was first sorted according to the 13 strata and then assigned to the replicate groups based on the order of sample (telephone number) selection. The calculation of replicate weights proceeded as follows.

First, each of the screened householders was assigned the appropriate final person-level base weight in each of the 51 replicate groups. In the next step, replicate base weights were adjusted to reflect the deletion of that portion of the sample which is excluded for formation of respective replicates (i.e., the full sample base weight of all nondeleted units in each replicate were multiplied by 51/50). Each of the resulting 51 sets of replicate base weights was then raked to the same control counts used for raking of the full sample weights.

Specifications for Within-Household

Retention Rates Memoranda

TO: Fauzia Tirmazi April 21, 2008
FROM: Mike Jones, Richard Sigman **MEMO:** S30 V1
SUBJECT: CTS 2008 Specifications for Within Household Retention Rates

This memorandum specifies the sample retention rates within cooperating households. The CTS 2008 sample targets are the following:

- 1,500 completed screener interviews per region,
- 1,500 extended interviews with African Americans
- 4,000 young adult extended interviews (18 to 29 year olds)
- 6,900 older adult extended interviews (30 plus year olds)

The sample plan is to retain all young adults (18-29 years old) in cooperating households for the extended interview. For older adults (30 years and older), retention rate are specified by smoker status and by race/ethnicity. Persons with unknown age, will be treated as young adults and included with certainty.

1. Roster

Rostering method for CTS 2008 is the same as previous cycles of CTS; that is, all household members will be rostered, including adults, teens and children. Roster all household members in a household. Each older adult member (30 years and older) is assigned a random number (RANDOM01-RANDOM15). The random numbers are preselected and included in the CATI load file. We use the preloaded random number to determine sample retention.

2. Older Adults

For adults (30 or older), the retention rate (for interviewing) depends on smoking status and race ethnicity. The smoking status is defined the same way as previous cycles of CTS using the screener items SC9(SMOKE100), SC10(SMOKENOW), SC11(SQUIT), SC12(S12QUIT). The method of recode is as follows:

Smoking status	Frequency of smoking	Responses to screener questions
Smoker	Current	SC10 = 1, 2 or (SC9 = 1, -7, -8 and SC10 = -7, -8)
Smoker	Recent former	SC9 = 1, -7, -8, SC10 = 3, SC11=1, and SC12 = 1

Smoker	5 Year former	SC9 = 1, -7, -8, SC10 = 3, SC11=1, and SC12 = 2, -7, -8
Nonsmoker	Long term quitter	SC9 = 1, -7, -8, SC10 = 3 and SC12 = 2, -7, -8
Nonsmoker	Zero or small amount smoker	SC9 = 2, and SC10 = 3, -7, -8

Race ethnicity is recoded from SC13 (HISPANIC), SC14 (ETHNBKGD) and SC15 (RACE). There is a hierarchical structure to the assignment of race as shown in the CATI screener specs. What follows is text from the CATI spec.

Black	If SC15 = 2
Asian	If SC15 = 3, 4, 5, 6, 7, 12
All others	All else

As SC15 (ENUM.RACE) is code-all-that-apply, the following priority will be used: Asian, Black and Others. If a Respondent answers White and Black, the person is treated as Black and sampled using the retention rates for Black. If a person answers Black and Asian, the person is treated as Asian and sampled using the retention rates for Asian. If there is no response of Black or Asian, the person is sampled using the retention rates for the All Other category.

The following table shows the retention rate by smoking status and race/ethnicity. We retain all smokers and black nonsmokers (retention rate 1.00). For other older nonsmoking adults, retain if the random number assigned is \leq the retention rate shown by smoking status and race. For example, for an Asian nonsmoker older adult, retain for interview if random number \leq 0.40.

Race/ethnicity	Response to screener items	Smoker retention rate	Nonsmoker retention rate
Black	If SC15=2	1.0000	1.0000
Asian	If SC15=3,4,5,6,7, 12	1.0000	0.6765
All others	Everyone else	1.0000	0.0671

TO: Fauzia Tirmazi November 14 , 2008
FROM: Mike Jones, Richard Sigman **MEMO:** S30.1 V1
SUBJECT: CTS 2008 Specifications for Within Household Retention Rates
CHANGES: Retention rate for Asian non-smokers changes to 1.0

This memorandum specifies the sample retention rates within cooperating households. The CTS 2008 sample targets are the following:

- 1,500 completed screener interviews per region,
- 1,500 extended interviews with African Americans
- 4,000 young adult extended interviews (18 to 29 year olds)
- 6,900 older adult extended interviews (30 plus year olds)

The sample plan is to retain all young adults (18-29 years old) in cooperating households for the extended interview. For older adults (30 years and older), retention rate are specified by smoker status and by race/ethnicity. Persons with unknown age, will be treated as young adults and included with certainty.

1. Roster

Rostering method for CTS 2008 is the same as previous cycles of CTS; that is, all household members will be rostered, including adults, teens and children. Roster all household members in a household. Each older adult member (30 years and older) is assigned a random number (RANDOM01-RANDOM15). The random numbers are preselected and included in the CATI load file. We use the preloaded random number to determine sample retention.

2. Older Adults

For adults (30 or older), the retention rate (for interviewing) depends on smoking status and race ethnicity. The smoking status is defined the same way as previous cycles of CTS using the screener items SC9(SMOKE100), SC10(SMOKENOW), SC11(SQUIT), SC12(S12QUIT). The method of recode is as follows:

Smoking status	Frequency of smoking	Responses to screener questions

Smoker	Current	SC10 = 1, 2 or (SC9 = 1, -7, -8 and SC10 = -7, -8)
Smoker	Recent former	SC9 = 1, -7, -8, SC10 = 3, SC11=1, and SC12 = 1
Smoker	5 Year former	SC9 = 1, -7, -8, SC10 = 3, SC11=1, and SC12 = 2, -7, -8
Nonsmoker	Long term quitter	SC9 = 1, -7, -8, SC10 = 3 and SC12 = 2, -7, -8
Nonsmoker	Zero or small amount smoker	SC9 = 2, and SC10 = 3, -7, -8

Race ethnicity is recoded from SC13 (HISPANIC), SC14 (ETHNBKGD) and SC15 (RACE). There is a hierarchical structure to the assignment of race as shown in the CATI screener specs. What follows is text from the CATI spec.

Black	If SC15 = 2
Asian	If SC15 = 3, 4, 5, 6, 7, 12
All others	All else

As SC15 (ENUM.RACE) is code-all-that-apply, the following priority will be used: Asian, Black and Others. If a Respondent answers White and Black, the person is treated as Black and sampled using the retention rates for Black. If a person answers Black and Asian, the person is treated as Asian and sampled using the retention rates for Asian. If there is no response of Black or Asian, the person is sampled using the retention rates for the All Other category.

The following table shows the retention rate by smoking status and race/ethnicity. We retain all smokers and black nonsmokers (retention rate 1.00). For other older nonsmoking adults, retain if the random number assigned is \leq the retention rate shown by smoking status and race. For example, for an Asian nonsmoker older adult, retain for interview if random number \leq 0.40.

Race/ethnicity	Response to screener items	Smoker retention rate	Nonsmoker retention rate
Black	If SC15=2	1.0000	1.0000
Asian	If SC15=3,4,5,6,7, 12	1.0000	1.0000
All others	Everyone else	1.0000	0.0671
